

Lab – GitHub Copilot – Prompts Engineering & Life Cycle

Ex1

Use github copilot for writing a whole application in java script for managing a University.

The whole application should be written with a **single file that already exists**

The university composed of a collection of Students.

Each Student has name, faculty and a collection of grades.

Any student can add a new grade (must NOT be negative), calculate the grades avg and can change faculty

The University can add and remove students, calculate the avg of all students grades avges and find the most excellent student.

- Get recommendation for a proper data structure for the application
- Set a proper role & goal.
- Verify that the student's grades avg calculation is the most efficient that can be.
- Instruct (use Chain-Of-Thought) the copilot how to implement the function that calculates avg of the students grades averages.
- Create documentation for all student's functions
- Create unit tests for student's grades avg calculation function
- Make a quick code analysis on the University code.
- At the end, try to convert the whole code to ONTHER programming language
